Acyl Chlorides | Nucleophilic Addition-Elimination (with amines)

Reaction

REACTANTS: Acyl Chloride and Amine (primary)

PRODUCT: (Secondary) Amide and Alkyl Ammonium Chloride

REACTION TYPE: Nucleophilic Addition-Elimination

Mechanism

The amine acts as a **nucleophile** due to the lone pair of electrons on the nitrogen atom attacking the carbon (with a partial positive charge) in the acyl chloride. A new carbon-nitrogen bond forms between the acyl group and the ammonia. The carbon-oxygen double bond breaks to a single bond, giving the oxygen a negative charge. The carbon-oxygen double bond reforms, carbon-chlorine bond breaks and a chloride ion is removed. Amine present removes H^+ ion from $-\text{RCON}^+\text{HR}'$ group. **Addition-elimination reaction.**

Notes:

- Ammonia produces a **primary amide** and ammonium chloride salt when reacted with acyl chlorides.
- Primary amines produce a **secondary amide** and an alkyl ammonium chloride salt when reacted with acyl chlorides.
- Secondary amines produce a **tertiary amide** and an alkyl ammonium chloride salt when reacted with acyl chlorides.
